AgentStream

AI agents pay each other per-second in USDC for data, compute, and content on Solana

The Problem & Our Solution

AI agents now call other agents and APIs autonomously, but payment rails are built for humans, not machine-speed transactions.

- Subscriptions and cards require human setup and can't bill per-second usage.
- Agents need to pay other agents instantly, without manual invoices or approvals.
- AgentStream opens on-chain USDC streams so agents pay only for seconds actually used.
- Built on Solana for fast finality and low fees at high transaction volume.
- Simple SDK lets any developer monetize an AI agent or API instantly.

How It Works

A requesting agent opens a Solana escrow stream to a provider agent; funds release per second as usage is metered.

- Agent A calls the AgentStream SDK to open a USDC stream to Agent B's wallet.
- On-chain escrow program locks funds and releases them proportionally to elapsed time.
- Provider agent meters usage (tokens, compute, data) while the stream updates in real time.
- Either side can close the stream anytime; unused escrowed USDC returns to the payer.
- Dashboard shows live streams, spend rate, and balances for monitoring and debugging.

Built with

Solana, Anchor, Rust, Solana Pay, USDC (SPL Token), Next.js, TypeScript SDK

Why Now & What's Next

Agentic AI and machine-to-machine commerce are exploding, and existing payment rails are too slow for agents transacting at machine speed.

- Autonomous agents increasingly call paid APIs and other agents without human intervention.
- Solana's speed and low fees make thousands of micro-payments per minute practical.
- Next: support more SPL tokens and stablecoins beyond USDC.
- Next: build a marketplace/discovery layer for paid agent services.
- Next: integrate natively with agent frameworks like LangChain and ElizaOS.
